NOVELTY - An interface layer is included between an insulating layer and a piezoresistor film in a sensing structure to inhibit diffusion therebetween in a sensing structure.
- DETAILED DESCRIPTION - The sensing structure comprises (i) a substrate, (ii) at least one electrical insulating layer, (iii) a thick-film piezoresistor, and (iv) an interface layer between the insulating layer and the piezoresistor, and comprising particulate alumina and zinc oxide suspended in a glass matrix and inhibiting the diffusion piezoresistor constituents into the insulating layer. An INDEPENDENT CLAIM describes a sensor as above for pressure measurement wherein the substrate is a steel alloy diaphragm.
- USE - The structure is a pressure transducer for e.g. automotive applications involving measurements in high pressure, corrosive fluids.
- ADVANTAGE - The performance of the sensor is improved by preventing the diffusion of glass frit components between the piezoresistor and insulating layers. The known arrangement using thick-film technology and a steel diaphragm is amenable to mass production techniques. (Dwg.1/12)

NOVELTY - A pressure-sense resistance film (50) is formed on a resistor pattern (40) connected between conductor patterns (20,30), on which a short circuit member (60) with press members (61) is formed. The resistance value between the conductors is varied by changing the resistance value along thickness direction of resistance film by pressing the short circuit member.

- USE - None given.

- ADVANTAGE - Structure and design property becomes simple thereby simplifying assembly and attains reduction in size. The texture of variable resistor in electric circuit becomes simple. Endurance and durability are improved. DESCRIPTION OF DRAWING(S) - The figure shows the schematic sectional view of variable resistor. (20,30) Conductor patterns; (40) Resistor pattern; (50) Pressure-sense resistance film; (60) Short circuit member. (Dwg.1/6)

The component includes a pressure sensitive film element (20) which is formed over a base material, comprises a pressure sense resistance film (23). A pair of electrode patterns (21) are provided at the either surfaces of the resistance film. An electrically conductive pattern (25) is provided at the top surface of the resistance film.

- A bullet (30) is provided on the surface of the pressure sensitive film element. A key top (40) is provided such that it presses the bullet member. By pressing the key top the bullet member and thereby the pressure sensitive film element is pressed and resistance between the electrode patterns is varied.

- ADVANTAGE - Simplifies assembling work of electronic component. Enables to easily vary resistance value of pressure sensitive film element. (Dwg.1/9)

The sensor has a pressure sensing element (20) provided at the lower surface of a dome like pressing part (11) of a film (10). The pressure sensing element includes resistance film (25) on whose either sides of electrode pattern (21,27) is formed.

- When the resistance film is pressed along thickness direction its thickness varies. The resistance between two electrode patterns also get varied.

- ADVANTAGE - Eases mfg technique. Avoids assembly error. (Dwg.1/11)

The element has a circular cylindrical housing (2) with a baseplate (3) and a bearing (4) for a rotary shaft (6) having an external thread (7) on to which a pressure disc (12) is screwed. The shaft passes through an elastically deformable body (11) around which the force-sensing resistor (8) has two polymer films with interdigitated electrodes.

- As the shaft is rotated the axial force exerted by the disc on the body is transmitted through the outer radial surface (25) to the resistor, producing a change in its resistance or voltage. Both the film and the body are insensitive to any moisture seeping into the housing.
- USE/ADVANTAGE As e.g. displacement pick-up in automotive technology, device guarantees precise functioning over long period without wear on contact elements. (Dwg.1/2)

A touch panel includes a substrate made of a transparent insulated material. A substrate conductive layer is formed on the substrate. A dot space is formed between the substrate conductive layer, and a contact conductive layer formed on the dot space and causing change of electric resistance by external contact on the dot space. The contact conductive layer consists of a photo-transparent organic conductive film.

- USE - As touch panel with contact conductive layer

- ADVANTAGE - Provides more efficient structure of touch panel when photo-transmittance and resistance value is about 30-800 ohm/square. The touch panel has economic advantage because it is capable of being used permanently it a photo-transparent organic conductive film is not damaged (Dwg.3/4)

The switch includes a planar substrate, an insulating spacer about a periphery of the substrate, and a planar cover. The cover in an active area carries an electrically conductive film designed to contact a conductive film carried upon an active area of the substrate. An insulating spacer and conductive dot are also located at some point within the active area to form a non-contacting rest area.

- Appropriate forces applied in a direction normal to the plane of the substrate or cover cause deflection, leading to contact between the cover and the substrate. The point of contact identifies intent, direction and magnitude.

- USE/ADVANTAGE - For vehicles, computers, appliances, toys and laboratory equipment. Provides highly sensitive switch which provides reliable indication of intent, direction and magnitude. (Dwg.1/3)

The pressure sensitive transducer comprises a first layer with a noninsulative layer deposited on it, and a second layer deposited adjacent and abutting the first (16, 18). This layer has a resistive surface with small points of raised material (18) deposited on it.
- The raised points of material maintain the separation of the two layers.
rs. The first layer makes contact with the second layer in response to an applied pressure (13) and by this provides a variable resistance between the two layers by deforming around the raised points.
- ADVANTAGE - Utilises conventional resistive film layer with smooth surface and consistent resistivity, employing printing and imaging technology to deposit pattern of nonconducting or semiconducting points of controllable, well-defined dimensions. (Dwg. 3A/8)

The computer joystick includes a force transducer. The transducer (10) has a lever (16). This is flexed by the user at its free end (14) while being connected to a substrate (20) at its lower end (16). The sensing element (18) has thick film strain gauges (24,26) detecting force components in the X and Y directions.

- The strain gauges are formed by screen printing thick film resistive material directly onto the substrate. Each gauge has a complementary gauge on the underside of the substrate. The sensing element is mounted on a support plate (28) and has electrical connections (70-74) on its surface.

- ADVANTAGE - Provides a small force transducer suited to computer joystick use and having good signal to noise ratios. (Dwg.1/11)

The computer input device includes an elastic actuator button of generally hemispheric shape. An applied force causing an indentation in a curved portion of the button is transmitted via the material of the button to cause a corresponding elastic bulging of a bottom, normally flat portion of the button and of a conductive film and resistive film which are attached to it. During such bulging, a portion of the resistive film is urged into contact simultaneously with two or three oppositely disposed conductive traces. This action can cause a cursor to be moved in a direction corresponding to the direction of force of the push when the device is attached to the proper circuitry.

- The amount of pressure applied to and transmitted through the elastic material of the button determines the size of the area of contact between the resistive film and the pattern of conductive traces and ultimately the speed and/or distance of movement of the cursor in that direction. A central post may protrude from the bottom of the button into a corresponding depression or hole in the base of the device so as to act as a contact or actuator for a separate switch so as to provide a function separately from or in concert with the other functions provided by the control.
- USE/ADVANTAGE - Is replacement for computer mouse, joystick or track ball and performs functions of any of these three input devices. Provides particular printed pattern of interdigitated conductors, a selected portion of which are actuatable according to direction and magnitude of force applied to single actuator button. The force sensor has an elastic beam and comprises first and second surfaces separated by a gap, each surface being formed in a silicon substrate. The first surface is capable of flexing in response to an external force, the second surface being stationary relative to the first and acting as a deflection stop. A resistor is formed on one of the surfaces and has two terminals with a current path between the two terminals.

- An electrode on the other surface acts as a shunt for that portion of

the resistor which comes into contact with the electrode. One of the surfaces includes a central beam located on a diaphragm, the central beam being at least about four times thicker than adjacent portions of the diaphragm. When flexing of the first surface occurs, a resistance in the current path between the two terminals changes in response to the external force.

- USE - Silicon pressure chip operating in a two-wire resistive mode. (Dwg.3/7)

The switch comprises a first electrode composed of a non-conductive flexible film (10) having a conductive film (10A) on one surface and a second electrode composed of a non-conductive film (12) having a conductive film (12A) on one surface facing the first electrode and a number of insulative spacers (14) mounted on at least one of the electrodes. The spacers (14) are of very small dimension -lateral dimensions of 50 microns or less and a height of 15 microns or less, whereby the insensitive zone areas of the switch are of reduced size. The spacers (14) may be formed from a photoresist. A protective coating of plastics containing metal or metal oxide particles may be formed upon the conductive film (10A). In a further embodiment, the conductive films (10A,12A) are coated with resistance layers of plastics containing metal or metal oxide particles and metal coated transparent balls of 5-10 microns diameter.

- (31pp Dwg.No.1/12)

DEAB- DE4020472 C

An electrode (9A) with a non conducting sheet (10) of flexible and optically transmitting material, has an inner layer of conductive material formed from gold, nickel, palladium or other suitable material. Connecting elements are formed (11A,11B) at both ends.

- The second electrode (9B) has a conductive thin layer (12A) on a non conductive substrate (12) that has a rigid form, e.g, glass. On the surface of the conductive layer are spacers (14) formed in an etching process. A probe can be moved across the top surface causing local deflections between spacers and causing the conductive layers to contact to generate outputs.

- ADVANTAGE - Simplifies surface switch panel.

- od (Dwg.3/12)

GBAB- GB2233499 B

A sheet-like switch comprising: a first sheet-like electrode composed of a non-conductive flexible substrate having a conductive film of metal or metal oxide on a surface thereof; a second sheet-like electrode composed of a non-conductive substrate having a conductive film of metal or metal oxide on a surface thereof, which first and second sheet-like electrodes are arranged one opposite to the other with said conductive films facing; and a multiplicity of insulative spacers mounted on one or both conductive films at predetermined spaced intervals, arranged to separate said first and second electrodes; which sheet-like switch is characterised in that: each spacer is attached to the or each respective conductive film by an intervening layer of plastics material containing dispersed metal or metal oxide particles and having embedded in its surface a multiplicity of protruding metal coated balls of 5 to 10 μ m diameter. The touch-control light dimming switch has a front cover plate (21) incorporating a flexible zone (23) which is depressed upon contact to close electrical contacts providing a corresp. signal used to adjust the power level supplied to the electrical load.
- Pref. the front cover plate has a flat smooth surface and is made from ABS plastics with an area of reduced thickness providing the flexible zone (23), which is depressed to operate a membrane voltage divider providing the signal representing the required light level. The selected lighting level may be indicated by an incorporated optical display.
- ADVANTAGE - Aesthetic appearance and simple operation. (13pp
Dwg.No.3/7)
- GBAB- GB2233841 B
A touch-operable power control device for controlling power from a source to a load, said device comprising, in combination : a) a cover plate having a planar and smooth front surface and an opposing back surface, a portion of said back surface being recessed to define a flexible web of material that overlies a pocket; b) a substantially rigid plate spaced from and parallel to said flexible web of material; c) touch-operable means located in said pocket and positioned between said rigid plate and flexible web for providing a signal in response to pressure applied to said flexible web; and d) circuit means for determine the power applied to said load in accordance with the location of the pressure applied to said flexible web. (Dwg.0/0)
- USAB- US5196782 A
The system to control power from a source to a load consists of a cover plate, a touch-operable device that is mounted behind a flexible area on the cover plate, and a power control circuit that responds in accordance with a signal generated by the touch-operable device. The system is operated by touching a point within the flexible area of the cover plate to activate the device. The system provides power over a continuous range of values, depending on the particular point at which the device is activated. Alternatively, the system operates as a switch, alternatively turning power on or off when any point on the flexible area is touched.
- The control circuit preferably includes an electronically adjustable voltage divider. The system is well-adapted to permit control of power to a load from multiple locations. The appearance of the front surface of the cover plate can be dictated entirely by aesthetic considerations and can, if desired, be entirely featureless.
- USE - Wallbox mountable power control. Load may be light source, e.g.:
incandescent or gas discharge lamp, or motor, etc. (Dwg.5/7)

Appts. comprises (1) a flexible **membrane** for activating electrical contact between first and second circuits in response to tactile pressure exerted on **membrane**. The **membrane** comprises one of circuit and a continuous topmost glass layer having sufficient flexibility to permit flexible movement of glass layer together with one circuit to a point of electrical contact with the other circuit when tactile pressure is applied to glass layer. The glass layer has sufficient elasticity to permit glass layer together with one circuit to return to a point of non-electrical contact with the other circuit when tactile pressure is removed from glass layer. (2) Support layer for holding other circuit stationary; and (3) spacer for spacing flexible **membrane** from support layer so as to prevent electrical contact between first and second circuits until tactile pressure is exerted. Pref. flexible **membrane** comprises a polyester layer adhesively joined at one surface to said glass layer, and where one circuit is carried by another surface of polyester layer which is opposite to one surface. The support layer comprises a polyester layer adhesively joined at one surface to an inflexible glass layer. The other circuit is carried by another surface of the polyester layer which is opposite to the surface joined to inflexible glass layer. USE/ADVANTAGE - A

membrane-type electrical control panel apparatus for activating electrical contact between a first and second electrical circuit by flexible movement of one of circuit means in relation to the other in response to tactile pressure exerted on membrane-type control panel apparatus, used for touch controlled appts. for voltage selection in control panels requiring high temp., resistant. Skin comprises two flexible dielectric film insulating layers (54, 58), a carbon-base electrically conductive compound (56) uniformly applied to one of the two facing film surfaces, and electrically conductive metal compound (62) applied to the other facing surface. The compounds are contiguous over the interface between the films, and the metal compound is applied selectively to form pairs of conductive regions spaced by a dielectric gap.

 - A constant potential difference is maintained between the regions of each pair, there is a flexible resilient fibre matting layer (66) attached to the outermost film surface and an elastically deformable outer layer (70) secured over the matting. A controller is responsive to current flowing between regions to regulate travel of the member. The films are pref. each a single sheet of polyester film and the metal compound is silver oxide.
 - USE/ADVANTAGE - For a robotic arm. It is inexpensive so that it can be applied over the entire arm surface, and enhances safety for workpieces, equipment and operators. (1/4)
 - GBAB- GB2189889 B

A moveable member having a tactile sensing skin including: a first flexible dielectric film forming a first insulative layer mounted with respect to the outside surface of the moveable member, and having a first surface facing outwardly away from said member; a second flexible and dielectric film forming a second insulative layer adjacent said first insulative layer, and having a second surface facing said first surface; a carbon base electrically conductive compound substantially uniformly applied to one of said first and second surfaces; an electrically conductive metallic compound

selectively applied to the other of said surfaces, whereby said metallic compound and carbon base conductive compounds are continuous over the interface between said first and second films, said metallic compound being selectively applied to form a plurality of discrete pairs of first and second electrically conductive regions and a dielectric gap between said conductive regions of each pair; a means for establishing a substantially constant potential difference between the first conductive region and second conductive region in each pair; a first matting of resilient fibre forming a first flexible layer attached to the outwardly facing surface of said second film; an elastically deformable outer layer attached to the outwardly facing surface of said first flexible layer; and a control means responsive to changes in the amount of electrical current flowing between said first and second electrically conductive regions, for controlling

travel of said member.

 AB - GB2064873 A
 A pressure responsive electric switch has at least one pair of first
 (104) and second (112) conductors in spaced-apart relationship with at
 least one pressure sensitive resistive conductor (106,114) is disposed
 in a position to interconnect the conductors when a force is applied.
 - The design may be incorporated in multiple touch switches having the
 conductors (220,240) disposed side by side or stacked one above the
 other. The resistive conductor may be made from molybdenum disulphide
 particles with a resin binder and may include powdered carbon.
 DEAB- DE3044384 C
 The pressure transducer uses a resistance element, exhibiting a
 resistance value which varies as a reciprocal of the applied
 perpendicular pressure. The resistance element has 2 semiconductor
 resistance layers (106,114) between 2 conductor elements (104,112),
 each carrying one of these layers.
 - Pref. the resistance layers are formed from molybdenum disulphide
 using particles with a particle size of between 1 micron and 10 micron
 suspended in a binder. At least one of the conductor elements is pref.
 elastic, or coupled to an elastically deformable membrane.
 - USE - For pressure-sensitive switch, e.g. for switch keyboard.
 ((Dwg.1/14))

The touch switch unit has a first semiconductor composition layer disposed on top of a first conductor layer which is affixed to a first base member. A second semiconductor composition layer opposing the first semiconductor in spaced relationship to it is disposed on a second conductor layer which is itself disposed on the bottom surface of a second support member. A third conductor layer is also disposed on the top surface of the second support member in opposing spaced-apart relationship to a fourth conductor layer disposed on the bottom surface of a third support member.

- The second and third support members and the affixed conductor layers and semiconductor layers are resiliently deformable in a transverse axis in response to a transverse touch force to thereby cause electrical contact between the second and third conductor layers to provide a closed switch and the first and second semiconductor to provide a second closed switch in series with a pressure sensitive resistance.

DEAB- DE3044384 C

The pressure transducer uses a resistance element, exhibiting a resistance value which varies as a reciprocal of the applied perpendicular pressure. The resistance element has 2 semiconductor resistance layers (106,114) between 2 conductor elements (104,112), each carrying one of these layers.

- Pref. the resistance layers are formed from molybdenum disulphide using particles with a particle size of between 1 micron and 10 micron suspended in a binder. At least one of the conductor elements is pref. elastic, or coupled to an elastically deformable membrane.

- USE - For pressure-sensitive switch, e.g. for switch keyboard.
